Systemic inflammation-associated proteins and retinopathy of prematurity in infants born before the 28th week of gestation. Invest Ophthal Vis Sci. 2017;58:6419-6428. DOI:10.1167/iovs.17-21931

RETINOPATHY OF PREMATURITY

Systemic Inflammation-Associated Proteins and Retinopathy of Prematurity in Infants Born Before the 28th Week of Gestation

Purpose. To assess the association between systemic levels of inflammation-associated proteins and severe retinopathy of prematurity (ROP) in extremely preterm infants.

Methods. We collected whole blood on filter paper on postnatal days 1, 7, 14, 21, and 28 from 1205 infants born before the 28th week of gestation, and measured the concentrations of 27 inflammation-associated, angiogenic, and neurotrophic proteins. We calculated odds ratios with 95% confidence intervals for the association between top quartile concentrations of each protein and prethreshold ROP.

Results. During the first three weeks after birth, high concentrations of VEGF-R1, myeloperoxidase (MPO), IL-8, intercellular adhesion molecule (ICAM)-1, matrix metalloproteinase 9, erythropoietin, TNF-α, and basic fibroblast growth factor were associated with an increased risk for prethreshold ROP. On day 28, high levels of serum amyloid A, MPO, IL-6, TNF-α, TNF-R1/R2, IL-8, and ICAM-1 were associated with an increased risk. Top quartile concentrations of the proinflammatory cytokines TNF-α and IL-6 were associated with increased risks of ROP when levels of neuroprotective proteins and growth factors, including BDNF, insulin-like growth factor 1, IGFBP-1, VEGFR-1 and -2, ANG-1 and PIGF, were not in the top quartile. In contrast, high concentrations of NT-4 and BDNF appeared protective only in infants without elevated inflammatory mediators.

Conclusions. Systemic inflammation during the first postnatal month was associated with an increased risk of prethreshold ROP. Elevated concentrations of growth factors, angiogenic proteins, and neurotrophins appeared to modulate this risk, and were capable of reducing the risk even in the absence of systemic inflammation.

proteins in systemic circulation in ROP etiology remains unclear.18,24,25

To our knowledge, no study has evaluated the risk of ROP in light of the relationship between potential sources of damage such as circulating inflammation-related proteins and potential protectors (e.g., IGF-1 and neurotrophins) during the entire first neonatal month in a large cohort. The ELGAN study provides an opportunity to evaluate these relationships.

METHODS

Participants (Table 1)
The ELGAN study is a prospective observational cohort study of children born before the 28th week of gestation at 1 of 14 participating hospitals in five states in the United States during the years 2002 through 2004.27 Mothers were approached for informed consent either upon antenatal admission or shortly after delivery. A total of 1506 infants born to 1249 mothers were enrolled. Infants with major birth defects or/and aneuploidy were excluded. The 1205 children who had at least one eye exam and one or more blood spots collected during the first postnatal month comprise the sample for this report. The institutional review boards of all participating institutions approved the enrollment and consent processes. The research presented here adheres to the tenets of the Declaration of Helsinki.

Newborn Variables (Table 2)
Estimate of gestational age was based on date of embryo retrieval, intrauterine insemination, or fetal ultrasound before the 14th week (62%). When any of these were not available, the estimate was based on fetal ultrasound at week 14 or later (29%); last menstrual period (7%); or gestational age recorded in the log of the neonatal intensive care unit (1%). Birth weight z-score was defined as the number of standard deviations above or below the median weight of infants of the same gestational age in a referent samples not delivered for preeclampsia or fetal indications.28 Infants with birth weight z-score between –2 and –1 were defined as moderately growth restricted, and infants with a z-score below –2 were defined as severely growth restricted.

Eye Exam
Definitions of ROP stages were those accepted by the International Committee for Classification of Retinopathy of Prematurity.27 In keeping with guidelines, the first ophthalmic logic examination was within the 31st to 33rd postmenstrual week.28 Follow-up exams were as clinically indicated until normal vascularization began in zone III, and the most severe ROP stage was recorded. We focused our analyses on prethreshold ROP, defined as any ROP in zone I, ROP stage 2 or 3 with plus disease, or ROP stage 3 without plus disease in zone II.29

Blood Spot Collection and Protein Measurement
Drops of blood were collected on filter paper (Schleicher & Schuell 903) on postnatal days 1 (range: 1–3 days); 7 (range: 5–8 days); 14 (range: 12–15 days); 21 (range: 19–23 days); and 28 (range: 26–29). All blood was obtained from the remainder of specimens obtained for clinical indications. Dried blood spots were stored at −70°C in sealed bags with a desiccant until processed. Details of the process of elution of protein from blood spots are provided elsewhere.30 The total protein concentration in each eluted sample was determined by bicinchoninic acid assay (Thermo Fisher Scientific, Inc., Rockford, IL, USA) using a multi-label counter (Victor 2; Perkin Elmer, Boston, MA, USA). The concentrations of each protein listed in Table 3 were measured at the Genital Tract Biology Laboratory at the Brigham and Women’s Hospital in the light of the relationship between potential sources of damage such as circulating inflammation-related proteins and potential protectors (e.g., IGF-1 and neurotrophins) during the entire first neonatal month in a large cohort. The ELGAN study provides an opportunity to evaluate these relationships.

Biomarkers of Retinopathy of Prematurity

### Methods

#### Participants (Table 1)

The ELGAN study is a prospective observational cohort study of children born before the 28th week of gestation at 1 of 14 participating hospitals in five states in the United States during the years 2002 through 2004.27 Mothers were approached for informed consent either upon antenatal admission or shortly after delivery. A total of 1506 infants born to 1249 mothers were enrolled. Infants with major birth defects or/and aneuploidy were excluded. The 1205 children who had at least one eye exam and one or more blood spots collected during the first postnatal month comprise the sample for this report. The institutional review boards of all participating institutions approved the enrollment and consent processes. The research presented here adheres to the tenets of the Declaration of Helsinki.

#### Newborn Variables (Table 2)

Estimate of gestational age was based on date of embryo retrieval, intrauterine insemination, or fetal ultrasound before the 14th week (62%). When any of these were not available, the estimate was based on fetal ultrasound at week 14 or later (29%); last menstrual period (7%); or gestational age recorded in the log of the neonatal intensive care unit (1%). Birth weight z-score was defined as the number of standard deviations above or below the median weight of infants of the same gestational age in a referent samples not delivered for preeclampsia or fetal indications.28 Infants with birth weight z-score between –2 and –1 were defined as moderately growth restricted, and infants with a z-score below –2 were defined as severely growth restricted.

#### Eye Exam

Definitions of ROP stages were those accepted by the International Committee for Classification of Retinopathy of Prematurity.27 In keeping with guidelines, the first ophthalmic
factor (BDNF); and basic fibroblast growth factor (bFGF). ELISA (R&D Systems) was used to measure IGF-1.

The concentrations of proteins measured in the ELGAN Study varied with gestational age category (23–24, 25–26, and 27 weeks), and postnatal day of blood collection (1, 7, 14, and 28). Because we were interested in the contribution of both high and low concentrations, and the concentrations of most proteins did not follow a normal distribution, the distribution of each protein’s concentration was divided into quartiles.

The proteins included were analyzed in two sets years apart with an “early epoch” of specimens (days 1, 7, 14, and 14) measured from 2010 to 2011, and a “late epoch” (days 21 and 28) from 2014 to 2015. Consequently, the two different sets were analyzed separately. We divided our sample into 30 weeks), postnatal day of blood collection (1, 7, 14, and 28), and measurement set (2009–2010, 2015). The infants were classified as being in the top quartile or not compared to their peers in the same group.

**Data Analyses**

We tested the hypothesis that infants who had a protein concentration in the top quartile on each day were no more likely than their peers to be given a diagnosis of prethreshold ROP. In this sample, both low gestational age and fetal growth restriction are associated with protein concentrations, and as well as with prethreshold ROP. Consequently, we adjusted for important confounders such as gestational age and birthweight.

**Results**

In this sample of infants selected on the basis of gestational age at birth, the incidence of prethreshold was 27% among children born during weeks 23 or 24, 14% among children born during the 25th or 26th weeks, and only 3% among children born during the 27th week of gestation.

**Early Epoch: Days 1, 7, and 14 (Table 4)**

The risk of prethreshold ROP risk was increased when day 1 concentrations of VEGFR-1 were in the top quartile and day 14 concentrations of MPO, IL-8, ICAM-1, MPP-9, and EPO were in the top quartile. In contrast, a reduced ROP risk was associated with top quartile concentrations of the following: day 1, SAA; day 7, VEGF and ANG-1; and day 14, RANTES, TSH, BDNF, and IL-1. Recurrent/sustained elevated concentrations (i.e., being in the top quartile on ≥2 days) of MPO and IL-8 in the early epoch (i.e., days 1, 7, and 14) were associated with increased ROP risk. A recurrent/sustained elevated concentrations of RANTES were associated with decreased risk.

**Late Epoch: Days 21 and 28 (Table 4)**

In the late epoch, an increased risk of prethreshold ROP was associated with a top quartile of the following proteins: day 21 TNF-α and bFGF; and day 28 SAA, MPO, IL-6, TNF-α, TNF-R1 and -R2, IL-8, and ICAM-1. In contrast, the top quartile concentrations of BDNF, NT-4, and ANG-1 on day 21 and 28, and PI GF on day 28 only, were associated with a reduced ROP risk.

Recurrent/sustained elevated late epoch concentrations (i.e., in the top quartile on both days 21 and 28) of CRP, SAA, MPO, IL-6, TNF-R1, TNF-R2, and IL-8 were associated with increased ROP risk. A reduced risk was associated with recurrent/sustained elevations of NT-4, BDNF, and ANG-1.

**ROP Risk Related to the Co-occurrence of Proteins on Day 28 (Table 5)**

We wanted to study how the co-occurrence of presumed “protective” and “damaging” biomarkers influenced the risk of prethreshold ROP. In Table 5, the Ang-2 × IL-6 +/− group has an OR of 2.0; since the lower bound of 95% CI does not include 1.0, the OR is significantly elevated compared to the referent group (−/−) at the P < 0.05 level. Conversely, the NT-4 × IL-6 (+/−) OR is 0.4; since the upper bound of the 95% CI does not

All analyses are adjusted for gestational age and birthweight z-score < −1. The last column of each epoch represents an elevated concentration on 2 or more of the days in the present epoch. Bold indicates odds ratios significantly >1 (P < 0.05) and bold italic indicates odds ratios significantly <1 (P < 0.05).

include 1.0, the OR is significantly reduced compared to the referent group (−/−) at P < 0.05 level.

On day 28, the ROP risk was reduced when the neurotropic factors NT-4 and/or BDNF were in the top quartile, but this risk reduction was observed only when the three inflammation-related proteins, IL-6, TNF-α, and ICAM-1, were in the lower three quartiles. This pattern was also observed for PIgF, but only for the inflammation-related protein ICAM-1. In contrast, when the concentration of TNF-α was in the top quartile, the risk of ROP was significantly elevated only when the concentrations of IGF-1, IGFBP-1, VEGF, VEGFR-1, VEGFR-2, ANG-1, ANG-2, or PIgF were not in the top quartile. A heightened ROP risk was also observed when IL-6 was in the top quartile simultaneously with a top quartile of ANG-2 or VEGFR-2 in the lower three quartiles. Top concentrations of ICAM-1 were associated with increased ROP risk only when VEGFR-2 concentrations were in the lower 3 quartiles.

ROP Risk Related to the Co-Occurrence of Proteins on Both Days 21 and 28 (Table 6)

Because persisting or recurrent inflammation appears to be more damaging than just isolated incidences of inflammation, we also studied the relationships between top quartile concentrations on two separate days a week apart. Infants who had top quartile concentrations of NT-4, BDNF, and ANG-1 on both days of the late epoch were at reduced risk of ROP when the selected inflammation-related protein (IL-6, TNF-α, or ICAM-1) was not in the top quartile on both days. Children who had a top quartile concentration of IL-6 on both days were at increased risk of ROP when the concentration of the neurotrophic protein (BDNF, IGF-1, IGFBP-1, VEGF, VEGFR-1, and ANG-1, or PIgF) was not in the top quartile on both days. Similarly, top concentrations of ICAM-1 were associated with increased risk of ROP only when VEGFR-2 concentrations were in the lower three quartiles. A heightened ROP risk was also observed when IL-6 was in the top quartile simultaneously with a top quartile of ANG-2.

DISCUSSION

Three of our findings are worthy of discussion. First, we found an increased ROP risk when some of the inflammation-related proteins were elevated. Second, infants who had top quartile concentrations of proteins with angiogenic and/or neurotrophic properties were at reduced risk of ROP, most prominently in the 3rd and 4th postnatal weeks (the late epoch). Third, there was a modulatory interaction between levels of proinflammatory proteins (e.g., IL-6, TNF-α, and ICAM-1) and a number of neuroprotective proteins. For some proteins (e.g., VEGFR-2, IGF-1) the protective effects were only apparent when we stratified the sample by the co-occurrence of the top concentration of the proteins associated with increased ROP risk (e.g., IL-6, TNF-α, and ICAM-1).
The pathogenesis of ROP is classically described as a 2-phase disruption of the retinal vascular development, where the first phase is characterized by cessation of retinal vessel formation and maturation, while new and aberrant vessel formation and growth occurs in the second phase. Prenatal phenomena have the potential to sensitize the developing retina, and subsequent postnatal stimuli/exposures together might constitute a “prephase” of ROP.12

We found that elevated concentrations of inflammatory mediators during the latter part of the first postnatal month (days 14–28) were most predictive of later ROP. As the second phase of ROP begins close to weeks 30 to 32 and the gestational age of the infants in our cohort varies, most of our protein concentration measurements were from specimens obtained before neovascularization begins or very early during neovascularization. Our findings thereby support the concept of a prephase that precedes phase 1.

**Inflammation Is a Risk Factor for Prethreshold ROP**

We identified TNF-α, TNF-R1, TNF-R2, IL-6, IL-8, SAA, CRP, ICAM-1, and MPO as proteins with potential to increase ROP risk. SAA and CRP are well-established liver-derived markers of systemic inflammation.30 TNF-α, and IL-6 are cytokines acting as primary initiators of inflammation following infection or tissue damage, activating macrophages and T-cells, as well as inducing angiogenesis and apoptosis.39 In the retina, TNF-α is involved in proliferative retinopathies as well as inflammatory diseases,40 and high plasma concentrations of IL-6, IL-8, and TNF-α have been associated with increased risk of ROP.17,41 Soluble TNF-receptors has potential to increase the half-life of TNF-α in the blood circulation.42 The inflammatory response includes upregulation of effector molecules such as chemokines (e.g., IL-8, RANTES), and adhesion molecules (e.g., ICAM-1).43 Because low vitreous and blood concentrations of RANTES have been found in children who developed severe ROP.17,41 RANTES might play a protective role. Our finding that high RANTES concentrations were associated with lower risk, although only in the early epoch, supports this inference.

**Neurotrophic Proteins Appear to Protect Against ROP**

We found a variety of biomarkers associated with reduced ROP risk, including IGF-1; angiopoietin (ANG-1); and neurotrophins (NT-4 and BDNF). These molecules are referred to as angiogenesis, and are capable of both neural and vascular protection and repair.45 Top-quartile concentrations of ANG-1 most consistently predicted reduced ROP risk on all days, except day 1. Both ANG-1 and ANG-2 are vascular growth factors important both in fetal life and after birth, where they

Measured on postnatal day 28 to children without a top quartile concentration of both proteins. The quartiles were determined within gestational age category and the day the blood was obtained. In these analyses, 4 groups are formed by the 2-protein combinations (i.e., +/+, +/−, −/+, −/−). The −/− group serves as the referent group for the other three. All analyzes are adjusted for gestational age and birth weight z-score < −1. Bold indicates odds ratios significantly > 1 (P < 0.05) and bold italic indicates odds ratios significantly < 1 (P < 0.05).
remodel the developing vasculature. Both are ligands of the Tie2 receptor, although one is in an agonist (ANG-1) and the other an antagonist (ANG-2). Whereas ANG-1 promotes vascular maturation and stability, ANG-2 initiates vessel instability and neovascularization.46,47 Our study further emphasizes ANG-1 as a possible protector throughout the whole prephase and phase 1 of ROP.

Neurotrophins belong to a family of growth factors that promote neuronal as well as oligodendrocyte survival and differentiation both in the central and peripheral nervous systems.48,49 Although the focus has been on the ability of neurotrophins to protect and repair the neural system, they can also have a beneficial effect on the vascular system.22,50 We found that high concentrations of the neurotrophins NT-4 and BDNF were associated with a reduced ROP risk. In the setting of top quartile concentrations of TNF-α, IL-6, and ICAM-1 on days 7, 21, and 28, top quartile concentrations of VEGF on those days were associated with lower risks of ROP than observed when VEGF concentrations were lower. These findings are probably reflective of what is seen in the retina, with suppression of VEGF expression during the first hypoxic phase of ROP, which coincides with the timing of the samples tested in this study. After the first phase, VEGF expression is upregulated and potentiated by growth factors such as IGF-1, resulting in proliferative ROP. It is at this point that intravitreous anti-VEGF agents can be given to effectively treat severe ROP.52-54 VEGF production can be stimulated by hypoxia, but systemic diseases, oxygen treatment and respiratory distress might also trigger VEGF production and release.55 From this we infer that maintenance of higher VEGF levels during the ROP prephase or phase 1 would be reflective of less vasocecssation, and thus might reduce ROP risk.

Looking at Inflammation and Protection Simultaneously

We examined the risk of ROP associated with concurrent high concentrations of inflammation-associated proteins and high concentrations of proteins with neurotrophic and/or angiogenic properties (angioneuins). This reflects our perception that one can best identify the contribution of an angiineurin in the presence of high concentrations of an inflammation-related protein, and that the contribution of high concentrations of an inflammation-related protein is most easily identified when the concentrations of angioneuins are low.

The most common pattern we found was characterized by an increased ROP risk when the concentration of an
angiogenesis. IGF-1 is also probably necessary for normal VEGF
suggests a primary role in repair, but also the possibility that
ROP risk only when these proteins failed to be elevated. This
damage caused by inflammatory proteins appeared to increase
were not risk-defining in the absence of inflammation, but the
concentrations of IGF-1 or IGFBP-1 to reduce the risk of ROP in
postnatal month convey information about ROP risk. Top
proteins related to inflammation and growth during the first
age group, the day the specimen was collected, and the year
measurements were made. Because the concentrations varied
among children who are comparable by virtue of gestational
other, as well as with proteins that have neurotrophic properties.58 One explanation
for the occurrence of elevated concentrations of inflammation-related, angiogenic, and neurotrophic factors (potential
proteins) is that a common antecedent upregulates all of them.59 Another is that one response (probably inflammation)
upregulates the other (protection) as a “self-defense” mecha-
nism. Without additional data about protein response dynamics it is impossible to distinguish between the two options, but we
think that the “self-defense” hypothesis is supported by our
finding effects of one in the absence of the other (i.e., a risk increase without inflammation in the absence of elevated
concentrations of protectors, and a risk decrease with elevated
concentrations of protectors in the absence of inflammation; Tables 5 and 6). When analyzed individually, IGF-1, IGFBP-1,
and VEGFR-2 showed no evidence of protection (Table 4).
However, when high concentrations of these proteins are evaluated in light of the concentrations of IL-6, TNF-α, and
ICAM-1, risk modulation was identified. We encourage others
to use this strategy. Top concentrations of the three proteins were not risk-defining in the absence of inflammation, but
the damage caused by inflammatory proteins appeared to increase
ROP risk only when these proteins failed to be elevated. This
suggests a primary role in repair, but also the possibility that
inflammatory mediators (e.g., IL-6 and TNF-α), downregulate
these proteins as one of the mechanisms of inflammation-
driven damage to the retina.
IGF-1 is important for fetal growth, including healthy retinal
angiogenesis. IGF-1 is also probably necessary for normal VEGF
function.60 Low systemic serum IGF-1 concentrations are
associated with increased risk of ROP, and have been used to
distinguish infants at risk of developing ROP.60-65 Hence,
exogenous IGF-1 supplements have been suggested as a potential
prophylaxis for ROP.24 Interestingly, lower plasma concentrations of IGF-1 binding protein (IGFBP-3) were found
in infants developing severe ROP.64 We did not find elevated
concentrations of IGF-1 or IGFBP-1 to reduce the risk of ROP
in the absence of inflammation as defined in this study.
We view inflammation as a complex phenomenon that
includes many proteins from multiple functional categories
affecting multiple systems.55-57 The individual inflammation-
related proteins measured are probably surrogates for many
unmeasured proteins involved in inflammatory processes. The
angioneurins included here (including IGF-1) are surrogates for
many unmeasured proteins involved in retinal maturation and
repair. Consequently, exogenous IGF-1 might not be able to
achieve all that is needed to enhance retinal maturation and
repair. On the other hand, we did find infants in the lower
three IGF-1/IGFBP-1 quartiles to be vulnerable when concen-
trations of the inflammatory mediators IL-6 and TNF-α were
higher. This is in keeping with the finding that inflammation
might be a factor that reduces the already limited IGF-1
production in the preterm newborn.68

Strengths and Limitations
Our study has several strengths. First, we obtained multiple
blood spots weekly during the first postnatal month. The
multiphased development of ROP underscores the importance
of assessing biomarker concentrations longitudinally, as differ-
cent biomarkers probably play different roles in the different
phases of the disease. Second, we measured the concentrations
of a diverse set of proteins, including cytokines, chemokines,
adhension molecules, a matrix metalloproteinase, and a diverse
set of growth factors. Third, we included more than 1000
infants, making it unlikely that we have missed important
associations due to lack of statistical power, or claimed
associations that might have reflected the instability of small
numbers. Fourth, the infants were selected based on gesta-
tional age, not birth weight, in order to minimize confounding
due to factors related to fetal growth restriction.69 Fifth, we
collected all of our data prospectively, thereby minimizing bias.
Finally, our protein data are of high quality,70-71 and have high
content validity.72-74

Our study also has limitations. As the blood-retinal barrier
surrounds the eyes, the concentrations of cytokines and
growth factors in blood do not necessarily reflect the levels
found in the retina and vitreous of the eye.75 On the other
hand, inflammation appears capable of reducing the effective-
ness of these barriers,76 making it difficult to estimate to what
extent circulating proteins influence the retina directly. Our
blood specimens were collected at time points in the early
postnatal period, corresponding to the prephase and 1st phase
of ROP. Subsequently, any biomarker levels or differences that
may occur later, at the time of phase 2 and maximal ROP
development, are still unknown.
The blood we measured was not whole blood, plasma, or
serum. Rather, we eluted blood that had been dropped or
blotted on filter paper. Because some spots are thicker than
others, we normalized our measurements to milligram of total
protein in the eluent. Since this is not equivalent to
measurements made in freshly obtained blood, our measure-
ments are not directly comparable to measurements obtained
from clinical laboratories. Therefore, we do not provide
picograms of each protein per milligram of total protein.
Moreover, we compared the concentrations of each protein
among children who are comparable by virtue of gestational
age group, the day the specimen was collected, and the year
measurements were made. Because the concentrations varied
with each of these, offering a number for each concentration
would be highly misleading.

In conclusion, we found that blood concentrations of
proteins related to inflammation and growth during the first
postnatal month convey information about ROP risk. Top
quartile concentrations of inflammatory mediators were
identified as risk factors for development of prethreshold
ROP, while the top quartile concentrations of proteins with
known angiogenic and neurotrophic properties were associat-
ed with a reduced ROP risk. This study adds to our knowledge
of the complex etiology of ROP development, and is, as far as
we know, the first study with such a wide variety of systemic
biomarkers in a large cohort of extremely low gestational age
newborns.
